## EXECUTIVE SUMMARY

## Executive Summary

Natural gas is a domestically produced, abundant and clean burning fuel that is primarily used for home heating, industry and power generation in the United States. According to the US Energy Information Annual Energy Outlook, natural gas used for transportation equates to less than $1 \%$ of total natural gas consumed. This percentage is expected to increase in the coming years based on the reasonable price of natural gas fuel compared to the relatively high price of petroleum based fuels. The biggest challenge to natural gas use for transportation overall is fleets cannot convert their vehicles without a place to fuel, and fueling stations are a risk to build without proven demand. In order for natural gas vehicles to become as popular as their petroleum powered counterparts, fuel must be available and convenient.

The Brewer-Garrett Company was hired in June of 2013 to complete a study on the feasibility of building a compressed natural gas (CNG) fueling station and converting multiple fleets in the community that would benefit from such a station. A group of partners in Seneca County collaborated to be a part of the study, providing detailed information on their existing vehicles including past and future driving forecasts and planned replacements. This group consists is a mix of private companies, city and county government departments and local schools.

## Section 1: Cost Benefit Analysis of CNG Infrastructure

The type of CNG infrastructure and where it can be placed can take many different forms. This section begins with mapping the location of each partner on one map to get a visual of placement possibilities. Then it describes the pros and cons of the two types of CNG fueling options, time-fill and fast-fill stations, and where installing each would make sense. The possibility of making the station open to the public is explored so average daily traffic will be taken into consideration.

Projected fueling units of each fleet are calculated in Section 2 of this report. The individual fueling volume is added together to project the total fuel volume for the station for the next five years. This five year demand is essential in determining the initial size of a station and a benchmark for its opportunity and success.

## Section 2: Opportunity Analysis of Partner Fleet Conversion

Every vehicle in each participating partner fleet is analyzed for the benefits of fuel conversion to CNG. This section explains the conversion options available on the market today and strategies for converting fleets. It then defines assumptions used in conversion analysis in regards to projected rates of gasoline, diesel fuel and CNG. The cost of conversions will be different for every type of vehicle due to engineering a conversion package for each type of vehicle, total number of like packages purchased, and fuel capacity. Assumed conversion costs for this analysis were broken down into 5 categories to incorporate all types of over 400 vehicles in the study. An overview of emission benefits, performance differences and CNG vehicle safety are also included in this section.

The report contains an individual opportunity analysis for each partner. These detailed analyses are found immediately following Section Three and each partner can skip directly to their personalized

Brewer-Garrett
report of their own fleet. The analysis takes into account miles driven in the past, fuel economy in miles per gallon (MPG), current regular routes traveled, the difference of current and projected fuel cost and projected conversion costs. Overall vehicle life and forecasted vehicle purchases are considered in the viability of conversion versus new vehicle purchases. The payback of each vehicle is determined on a high, medium and low cost difference between the price they pay for conventional fuel and the projected price of CNG. For partners with immediate opportunity, sample cash flows are created to show potential 10 year savings.

## Section 3: Shared Natural Gas Purchasing Power

The larger the volume of throughput for the CNG station, the lower rate the utility will provide for the partners. This is a significant reason for the community to join together in this shared project. Natural Gas is purchased from utilities in units of a thousand cubic feet (MCF). When enough demand is created at the station ( $18,000 \mathrm{MCF}$ ), users will be sharing in the best possible rate available from the utility, which will mean lower prices per unit of CNG.

## Partner Map

## COST BENEFIT ANALYSIS OF NG INFRASTRUCTURE

## Section 1: Cost Benefit Analysis of CNG Infrastructure

### 1.1 Mapping of Partners and Natural Gas Lines

Natural gas infrastructure must be strategically located to serve all of the potential CNG fleets in the study. Convenience of fueling for vehicle operators helps to mitigate the stresses of changes to daily routines and fleet managers do not have to pay operators for additional time to drive extra miles to the pump. The partner map on page 5 shows where each partner is located. The main grouping of fleets is located in and around Tiffin, OH . Figure 1.1.1 draws out the strategic location of medium pressure natural gas lines located in Tiffin, OH. The selection of these highlighted areas for construction of CNG infrastructure is explained in Section 1.3.

Figure 1.1.1 - Location of Medium Pressure Gas Lines in Tiffin, OH

Seneca East Local Schools parks their fleet of school buses at a garage in Attica, OH. Due to its distance away from the ideal location of a station in Tiffin, OH, separate CNG infrastructure would serve the bus fleet more effectively. Figure 1.1.2 maps the location of medium pressure natural gas lines near the bus garage. The yellow line is located very near the southeast corner of the bus garage property.

Figure 1.1.2 - Location of natural gas line by Seneca East bus garage

### 1.2 Fast-Fill vs. Time-Fill Stations

CNG fueling infrastructure options available:

## Time-Fill Station

Time-fill stations can be characterized as fueling while a vehicle is parked. This setup is ideal for a fleet of vehicles that are parked overnight or for long periods of time outside at a home location. Natural gas is compressed and distributed to individual parking spaces through a series of poles and hoses. Time-fill stations require a lower capital investment than fast-fill stations but are limited by fueling capacity and time it takes to fill the fuel tank. An example of this scenario would be a school bus driver runs a daily route and at the end of the day connects a hose to the vehicle and by the morning has a full tank of CNG.

Source: US Department of Energy
http://www.afdc.energy.gov/fuels/natural gas cng stations.html

Figure 1.2.1 - Visual Representation of Time-Fill and Fast-Fill Fueling Stations

## Fast-Fill Station

A fast-fill fueling station dispenses CNG at a rate and overall experience similar to existing gasoline and diesel stations. Fast-fill stations are necessary when dealing with multiple fleets located in different locations and public access. Fast-fill stations require a larger initial capital investment but have the ability to spread costs over a larger pool of consumers by being available to be used by more people.

## Combination-Fill Station

A combination-fill station combines a fast-fill station with time-fill availability in the same location. This setup is ideal for a large vehicle fleet that wants to invest in CNG infrastructure for its own fleet, and also wants to make it available to other users to recoup capital costs and develop community infrastructure. Another advantage of a combo-fill station is that a fleet can use the time-fill option when it has the time, but top off or fill at the fast-fill pumps when time is constrained.

### 1.3 Alternative Fueling Units Explained

Units of measure for traditional vehicle fuel in the United States are provided in gallons for gasoline and diesel. While the properties of liquids accurately allow for dealing with them in terms of volume, gases can occupy a different amount of space depending on the temperature and pressure. CNG used for vehicles is natural gas compressed to 3600 psi; therefore standardized terms are used to compare fuels based on how much energy is contained in the fuel and not the volume it occupies.

## Gasoline Gallon Equivalent (GGE)

A GGE refers to the amount of energy in the volume of one gallon of gasoline.
1 GGE = 114,000 BTU

## Diesel Gallon Equivalent (DGE)

A DGE refers to the amount of energy in the volume of one gallon of diesel fuel.
1 DGE = 129,500 BTU = $1.136 \times$ GGE

| Fuel Type | Unit of Measure | BTUs/Unit | Gallon Equivalent |
| :--- | :--- | ---: | :--- |
| Gasoline (regular) | gallon | 114,100 | 1.00 gallon |
| Diesel \#2 | gallon | 129,500 | 0.88 gallons |
| Biodiesel (B100) | gallon | 118,300 | 0.96 gallons |
| Biodiesel (B20) | gallon | 127,250 | 0.90 gallons |
| Compressed Natural Gas (CNG) | cubic foot | 900 | 126.67 cu. ft. |
| Liquid Natural Gas (LNG) | gallon | 75,000 | 1.52 gallons |
| Propane (LPG) | gallon | 84,300 | 1.35 gallons |
| Ethanol (E100) | gallon | 76,100 | 1.50 gallons |
| Ethanol (E85) | gallon | 81,800 | 1.39 gallons |
| Methanol (M100) | gallon | 65,800 | 2.01 gallons |
| Methanol (M85) | gallon | 1.74 gallons |  |
| Electricity | kilowatt hour (Kwh) | 3,400 | 33.56 Kwhs |

Table 1.3.1 - Alternative Fuel Energy Equivalents

### 1.4 Strategic Placement of Fueling Stations

The first step in locating ideal sites for fueling infrastructure starts by analyzing the partner map on page 5. The main grouping of fleets is located within 4 miles of each other in the City of Tiffin. This map shows how one fast-fill station could support all of the fleets in the Tiffin area. To locate a possible fastfill station in Tiffin, OH two main factors need to be addressed: the location of existing natural gas lines and the best location based on fleet traffic.

Installing new gas lines can represent a large capital investment, therefore placing a station near existing gas lines has the potential for a quicker install time and less initial cost. In order to get the natural gas into onboard CNG storage at 3600 psi, compressors are staged and store the gas at a higher pressure to handle instantaneous fueling demand. Therefore, the higher the pressure of the incoming CNG, the more efficient and quickly the station can compress the gas for use. Medium pressure natural gas lines are found throughout the city and near strategic areas for a fast-fill fueling station (high pressure is not available in the area). According to the Tiffin Loop Road Feasibility Study in 2002, the area with the highest Average Daily Traffic, especially for high volume users such as trucks is along US 224 between the intersections of SR 18 and SR 100. Medium gas pressure natural gas lines are highlighted in Figure

### 1.1.1 along this route.

An ideal parcel of vacant land has been located near medium pressure gas lines on CR 54 near US 224. The lot is 4.7 acres and already cleared and ready for construction. It can be developed large enough for larger vehicles to navigate, accommodate fueling traffic, and leave room for capacity expansion as popularity grows.

Seneca East High School is located roughly 15 miles from the center of the main grouping of fleets with its bus garage located 2 miles east, which is farther away from Tiffin. Their potential converted school bus fleet could not be solely supported by a fast-fill station located in Tiffin. Seneca East's school bus fleet runs regular routes in accordance with the school schedule, and returns to the bus garage when not driving and at the end of the day. Due to its fleets' route pattern, and because they park outside in the same location every day, Seneca East has an opportunity to install its own time-fill station located at the exterior of the bus maintenance garage. A medium pressure gas line is located near the property shown in figure 1.1.3. The yellow line represents the medium pressure line running up Venice Street waiting to be taken to the bus property. By fueling as the bus is parked, the fueling time is reduced for operators and they benefit with a cleaner fueling experience.

### 1.5 Quantity of Fueling Units

In order to design the size of the station needed by the partners in the study, the projected fueling needs of each entity must be determined. In the tabs of this report, all of the vehicle fleets are analyzed by miles driven, age, and payback potential. Table 1.4.1 combines the projected needs of the partner fleets for a 5 year period.

| Year | Projected CNG Use (GGE) |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Seneca Medical | TPC | Arnold Vending | SCAT | Public | Sub Total | School Buses | Total |
|  | 46,800 | 32,750 | 28,350 | 35,000 | 21,000 | 163,900 | 19,322 |  |
| 2 | 54,600 | 36,025 | 37,800 | 42,000 | 22,050 | 192,475 | 25,762 | 218,237 |
| 3 | 58,500 | 39,300 | 47,250 | 49,000 | 23,153 | 217,203 | 32,202 | 249,405 |
| 4 | 66,300 | 42,575 | 47,250 | 52,500 | 24,310 | 232,935 | 38,642 | 271,577 |
| 5 | 70,200 | 45,850 | 47,250 | 52,500 | 25,526 | 241,326 | 45,082 | 286,408 |
| Total | 296,400 | 196,500 | 207,900 | 231,000 | 116,038 | $1,047,838$ | 161,010 | $1,208,848$ |

Table 1.4.1 - Potential CNG Use

The fast-fill fueling station in Tiffin, OH will also be open to the public. In sizing the station, CNG pumped by entities who are not partners in this study are taken into consideration. Fueling sales from the City of Dublin station in Columbus, OH were analyzed for the added fueling their station has experienced. These numbers were adjusted for the population difference of Dublin and Tiffin and are shown for a 5 year period. The initial CNG use in year one was escalated 5\% per year to project for 10 years.

School buses also have to be considered in the sizing of the fast-fill station. Although school buses consume a large amount of fuel, the available CNG school buses are sold a very high premium. The price difference for a like-to-like CNG school bus is approximately $\$ 40,000$ more than its diesel counterpart. Despite the high initial cost, CNG school buses have the potential to pay back over their life cycle, but in most cases they break even. The school bus market is advancing rapidly, and with engine manufacturers coming out with more appropriate sized engines than current larger duty forced into the buses now, the premium could be reduced to a cost that will generate significant savings. Also, funding is available through grants for CNG school buses. Even with their high cost, buses will be sought after by schools with accessible fueling infrastructure.

### 1.6 Design Considerations of the CNG Fueling Station

The 5 year forecast of CNG use in Table 1.4.1 is used to determine the initial sizing options of the fast-fill fueling infrastructure. Stations should be built with future expansion in mind as CNG demand in the area has the potential to grow. The key is to build the station large enough to handle initial oncoming load, while keeping it small enough to keep the capital investment at an affordable level. The projected CNG demand for the station in year 1 is 183,000 GGE, while after 5 years it grows to 286,000 GGE. This 5 year forecast should be the target size of the station and the ideal station capacity for this study ranges between 250,000 to 300,000 GGE/year.

This new station will be the only place to fuel a CNG vehicle in a 20 mile radius. Therefore, redundancy is a major issue for the building of the station. Redundancy is achieved by designing the station with multiple pieces of equipment so that if a compressor fails, vehicles will still be able to be fueled. Although building redundant equipment raises the initial cost of the station, the reliability will be a selling point to fleets in the area who are weighing conversions of their fleets to CNG.

The physical footprint of the CNG station must also be taken into consideration. The largest vehicles in the study that have a favorable payback are tractors with trailers. The station must be large enough to handle multiple tractors at a time plus space for overflow should all the installed dispensers be occupied at the same time so as not to disturb traffic patterns. There also needs to be enough room for these large vehicles to maneuver at the station.

## OPPORTUNITY ANALYSIS PARTNER FLEET CONVERSION

## Section 2: Opportunity Analysis of Partner Fleet Conversion

### 2.1 Types of CNG Vehicles

## Dedicated

A dedicated CNG vehicle is powered only by CNG. CNG is the only fuel stored on the vehicle and the engine system can only burn CNG.

Bi-Fuel

A bi-fuel vehicle is an "OR" vehicle. CNG and gasoline are stored on the vehicle in separate fuel systems. The switch of the fuels can be automatic or manual. For example, when CNG is present, the vehicle will default to burning it for maximum savings. If the CNG tank is emptied while driving, it automatically and seamlessly switches to burning gasoline. The switch can also be made with a manual switch by the vehicle operator.

## Dual Fuel

Dual Fuel vehicles can be thought of as "AND" vehicles. Because diesel engines use compression for combustion, they cannot be converted to burn exclusively natural gas which needs a spark plug to cause ignition. Therefore, these vehicles inject roughly a 50-50 split of CNG and diesel for power, but in some cases a higher ratio of CNG to diesel fuel can be achieved (60-40, 70-30, etc...). Dual Fuel vehicles cannot run on CNG alone, but if the CNG tank is empty, they will operate solely on diesel.

Each fleet operator must decide if converting vehicles to CNG is right for them. If it is, the next step is to develop a conversion strategy. One way to convert a fleet is to completely replace all petroleum powered vehicles with dedicated CNG powered vehicles. This method will see the largest annual savings immediately, but costs the most up front to implement. Additionally, there is always the risk of the vehicle running out of fuel in a remote location far from any CNG stations. Furthermore, by purchasing all new vehicles, the displaced vehicles must be sold or discarded and fleet managers might not recoup their residual value.

For some fleets, a hybrid conversion strategy works best. An example would be to convert existing vehicles using bi-fuel or duel fuel conversions where the payback is shorter than the remaining vehicle life. Older vehicles not initially converted are replaced with new CNG powered models as they retire.

### 2.2 Existing Fuel Rates

In this analysis, current fuel rates are taken at the rate provided by each partner. For reference, the average retail fuel prices for the past 13 years are displayed in Figure 2.2.1 according to the Alternative Fuels Data Center. Keep in mind that the fuel prices are in cost per GGE, so energy wise, diesel fuel and gasoline are almost equal in price.

Figure 2.2.1 - Past and Current Retail Fuel Prices
Just looking at Figure 2.2.1, it is easy to see the allure of using natural gas as a vehicle fuel. Ever since late 2003, CNG has been the more affordable fuel for vehicles. As this gap has spread, CNG technology has progressed and more stations are being constructed throughout the country.

Federal excise taxes are imposed on liquid fuels such as gasoline and diesel. Public entities are exempt from paying such taxes. The public entities pay approximately $\$ .50$ less per gallon of fuel than the private entities as illustrated in the individual opportunity analyses.

### 2.3 Projected Fuel Rates

The projected price paid for CNG by the partners in this study depends on many variables. The main components in the price of CNG are natural gas, electrical compression, operations and maintenance, and a capital amortization component to pay off the initial investment. An example of what a fuel rate could look like is displayed in Table 2.3.1.

| CNG Cost Component | per GGE |
| :--- | ---: |
| Natural Gas Cost | $\$ 0.75$ |
| Electric Compression | $\$ 0.15$ |
| Operations and Maintenance | $\$ 0.40$ |
| Capital Amortization | $\$ 0.50$ |
| Total CNG Cost | $\$ 1.80$ |

## Table 2.3.1 - Example Price of a Cost of CNG per GGE

Depending on how the station is engineered, built and funded the costs in Table 2.3.1 could change. The analysis in this report takes CNG rates on a low, medium and high case. Savings calculated are based on the difference of the current rate of fuel and three projected rates for CNG. Figure 2.3.2 shows the fuel price projections from the Annual Energy Outlook 2014 Early Release. This graph effectively shows that the price disparity of petroleum fuels and CNG will remain pronounced for the foreseeable future.

Figure 2.3.2 - Fuel Price Projections to 2040

COO

### 2.4 Cost of Conversion

Payback for each conversion depends on two factors. One is the difference of the current fuel price paid and the new cost of CNG, and the other is how much money is paid for the vehicle conversions. With the long list of vehicles in this study, the CNG conversion cost was broken down into 5 different categories. They are listed below in Table 2.4.1.

| Conversion type | Code | Cost |
| :--- | :--- | ---: |
| regular bi-fuel | A | $\$ 8,000$ |
| large bi-fuel | B | $\$ 10,000$ |
| regular dual-fuel | C | $\$ 12,000$ |
| large dual fuel | D | $\$ 20,000$ |
| school bus incremental | E | $\$ 40,000$ |

Table 2.4.1
The code listed in the table corresponds to the projected type of conversion listed in the analysis tabs. These costs are simplified for this analysis and are meant to give an approximate idea of what to expect. When discussions begin to take place about converting vehicles, each vehicle or type of vehicle will get a custom conversion setup and cost.

The payback of the vehicle conversion must also take the residual value of the components into consideration. One of the largest portions of the conversion costs is the price of the CNG tanks themselves. Correct sizing of the tanks based on range is the first way to keep cost down, but the tank's value after the vehicle is retired must also be considered. CNG tanks are rated for 20 years of useful life. This rating cannot be extended, but in almost all cases the tanks in a conversion will outlast the life of the vehicle. Therefore, each vehicle conversion system will be modularly engineered to be able to remove the expensive part of the conversion and reuse it on the next vehicle that takes its place. For example, most vehicles in this study with heavy use are taken off the road or used as spares after 10 years on the high end. In this example, the tanks in the conversion can serve at least two (2) life cycles of vehicles.

### 2.5 CNG Emissions, Performance and Safety

## Emissions

Natural gas $\left(\mathrm{CH}_{4}\right)$ is a low carbon fuel and burns cleaner than gasoline $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ and diesel $\left(\mathrm{C}_{16} \mathrm{H}_{34}\right)$. According to the California Air Resources Board (CARB) using natural gas as a vehicle fuel can reduce greenhouse gas emissions by 20-30\%.

## Performance

CNG vehicle performance is similar to their gasoline counterparts in normal driving conditions. One thing to keep in mind is that CNG tanks are pressurized, so where gasoline vehicles perform the same until empty, CNG vehicles gradually drop in power as the pressure reduces.

The only passenger CNG vehicle sold on the market, the 2012 Honda CNG, is a dedicated vehicle with fuel efficiency of 27 city/38 highway. Compare that with a similar gasoline powered 2012 Honda Civic of 28 city/ 39 highway fuel efficiency. In this case, fuel economy is barely affected, but the CNG version has less power.

As for school buses, the Bluebird CNG powered bus has 250-280 HP while the equivalent diesel version comes in at 200-280. The equivalent HP is due to the CNG engine being larger to create the same amount of power. This fact, along with the slightly heavier CNG tanks over diesel tanks reduces the overall fuel economy of the CNG powered buses from 5-15\%.

Dual fuel vehicles actually experience a significant increase in power over diesel only versions. Fuel economy in this setup is unchanged or slightly better.

## Safety

Natural gas vehicles are very similar to gasoline and diesel vehicles. The majority of the vehicle remains unchanged other than the fuel distribution system. The tanks are extremely durable and have strict standards for tank safety. Tanks are US Department of Transportation approved with expiration dates to assure tank integrity over time. Regular visual inspections must be performed, and since they are so rugged, damage to the tank will be noticeable by a trained inspector.

Properties of the natural gas itself make it safer than gasoline or diesel. CNG is lighter than air and dissipates into the atmosphere if a leak occurs, where liquid fuel pools on the ground as a fire hazard. In order for natural gas to ignite, the correct proportion of gas in the air must be present, between 5 and $15 \%$, and with natural gas dissipation, this concentration does not happen for long. The ignition temperature is relatively high for natural gas, almost double that of the ignition temperature for gasoline.

Re-fueling a CNG tank is a much cleaner experience than fueling with a liquid fuel. Because it is lighter than air, on the off chance some gas does escape during fueling, it dissipates into the air instead of spraying out of the tank or getting on hands and clothes.

## SHARED NATURAL GAS PURCHASING POWER

## Section 3: Shared Natural Gas Purchasing Power

Building one fast-fill fueling station to serve multiple partner needs creates a better position in negotiating with the natural gas company, and in turn achieves a better CNG rate for everyone. Deposits are paid for the installation of natural gas pipeline infrastructure expansion to the gas utility. When the utility recognizes large oncoming use, this deposit is typically waived.

The rate paid to the utility is also dependent on volume of commodity use. For a natural gas use of over 18,000 MCF per year with at least $50 \%$ of the use coming in the summer (profile of a public CNG station), the account qualifies for a special LGS rate. This shared natural gas use could mean a reduction of $\$ .10$ to $\$ .20$ per GGE paid at the pump.

Table 3.1 shows the amount of natural gas used per year based on how much fuel is pumped. The target amount fuel use at the station to qualify for the LGS rate is 161,871 GGE.

| GGE/year | MCF/year |
| :--- | ---: |
| 100,000 | 11,120 |
| 125,000 | 13,900 |
| 150,000 | 16,680 |
| 161,871 | 18,000 |
| 175,000 | 19,460 |
| 200,000 | 22,240 |

Table 3.1 - Natural Gas Use In Terms of Fuel Pumped

Brewer-Garrett

## Tab 1: City of Tiffin

## City of Tiffin CNG Opportunity Analysis

## Police Department

Scheduled Replacement: 2 new cruisers per year

The City of Tiffin Police Department has a fleet of 14 vehicles. Eight of these vehicles drive regular patrols and cover a significant amount of miles per year. The Police Department buys gasoline and diesel tax free, therefore they pay a relatively low rate for fuel. Vehicles are changed out at a rate of approximately 2 cruisers per year and ideally at 90,000 miles or 3 to 4 years. The payback of a conversion under these conditions is break even at best because of the continual replacement of vehicles at low miles. There are other issues hurting the opportunity including a reduction in trunk space for the CNG tanks, which is where officers store their gear. Also, the officers indicated they base vehicle purchasing decisions on results of tests conducted by the Michigan State Police Vehicle Evaluations. As of now, they have not conducted tests on natural gas vehicles. The other six vehicles do not drive enough miles to be candidates for conversions.

Conclusion: It is not recommended that the Tiffin Police Department convert their existing vehicles to run on CNG. However, options such as using interceptors, an SUV type police vehicle with more trunk space, or a reduction of gear could make CNG powered vehicles viable to Tiffin Police in the future, contingent on positive feedback from the Michigan State Police Vehicle Evaluation.

## Tiffin Fire Rescue

Scheduled Replacement: 1 new engine in 3 years
1 new command vehicle in 2 years
Tiffin Fire Rescue maintains a fleet of 12 vehicles located in multiple locations. Overall, none of the vehicles in the fleet drive enough miles per year to justify the conversion to natural gas. The fire department receives fuel tax free making their rate relatively low. Also, the chief indicated that reliability is seen as the top priority for the fire fleets vehicles. Although the natural gas conversions are reliable,
 adding another point of complexity to the fuel system is not desired.

Conclusion: It is not recommended that Tiffin Fire Rescue should convert their vehicles to CNG at this time.

## City of Tiffin Public Works

5 year Scheduled Replacements: New sweeper, dump truck, backhoe, jet truck and pickup

The City of Tiffin Public Works maintains a fleet of 21 vehicles. They range from medium to heavy duty and mainly travel in the city limits of Tiffin, OH. Some are seasonal vehicles such as the tractor and backhoe. Although some of the vehicles are used every day, they do not get driven a significant amount of miles. The information provided did not include the odometer readings of all vehicles, but during the interview it was clear that the light use of these vehicles does not fit the profile of successful conversion candidates.

Conclusion: It is not recommended that the City of Tiffin Public Works should convert their existing vehicles to CNG at this time. Sweeper trucks are generally a good prospect for a CNG and the replacement in the 5 year forecast should be evaluated as a new purchase.

## City of Tiffin Public Works

## Tab 2: Seneca County

## Seneca County CNG Opportunity Analysis

## Seneca County Sheriff Department

Scheduled Replacements: 2 cars per year
The Seneca County Sheriff Department faces many of the same challenges for CNG fuel conversion as the Tiffin Police Department. The sheriff explained that the trunks of the cruisers are used almost as a locker for the officers. They are always packed with equipment. Plus, as all of the public entities, the relatively low gasoline prices paid due to being tax exempt makes for a longer payback. Some vehicles do drive a significant amount of miles, but CNG is not a good solution for the Sheriff department.

Conclusion: It is not recommended that the Seneca County Sheriff convert their fleet to CNG at this time.

## Seneca County Engineer

Scheduled Replacements: unknown
The Seneca County Engineer has a fleet of 43 vehicles. The average age of the fleet is over 12 years old. From this, it is assumed that most of the vehicles do not cover a lot of miles per year.

Conclusion: It is not recommended that the Seneca County Engineer convert their fleet to CNG at this time based on the information provided.

## Seneca County Department of Disabilities (DD)

Scheduled Replacements: 3 buses and 3 transit vans in the next 5 years
The Seneca County Department of Disabilities has a fleet of 8 transit vans and 12 school buses that service 16 daily routes. What sets the DD apart from most other schools is that they transport students from the entire county and they operate year round. With this increased usage, some of these vehicles are candidates for conversion. Vehicles are replaced with the schedule of 250,000 miles or 12 years.

The cost of CNG school buses currently carries a \$40,000 premium over a like for like diesel bus and at that price, the vehicle will pay off by the end of life. CNG school bus technology is advancing as the industry grows. New engines are being developed especially for school buses that will bring down the premiums in the future. This development is happening rapidly, and as the premium decreases the overall savings for the school increases. Financial incentives are also available to schools for the purchase of new CNG school buses.

Conclusion: Seneca County DD should convert its bus fleet to CNG with financial incentives. The CNG buses should be placed on the longest daily routes to maximize savings. As the cost of CNG buses decreases, Seneca County DD should replace retiring buses with CNG powered versions. Also, converting existing transit vans and purchasing new CNG vans should be considered.

## Other County Departments

This category covers the county departments that are not covered in the departments above. This includes: Clerk of Courts, Crosswaeh, Dog Warden, EMA, EMS, Job and Family Services, Juvenile Court, Maintenance, Soil and Water, Veteran Services, and the Youth Center. This fleet contains 72 vehicles. Out of all of these vehicles, only a few of them might break even before they are replaced, and none are ideal candidates for conversion based on economics. As the popularity of CNG grows and the price of conversions and new CNG vehicles decreases, it might make sense to replace some with a CNG vehicle, but at this point, these are not good candidates for conversion.

Conclusion: It is not recommended that these County Departments convert their vehicles to CNG at this time based on economics, but added benefits of decreased emissions and supporting the community CNG station could play a role in evaluating feasibility.

## TAB 3: Tiffin City Schools

## Tiffin City Schools CNG Opportunity Analysis

Scheduled Replacements: 10 new buses in the next 5 years ( 2 per year)

Tiffin City Schools has a large fleet of 25 school buses and 12 non-school buses. Of the 25 school buses, 18 run daily routes during the school year and seven are kept as backups. The routes vary in distance, but on average they drive 15,000 miles per year. With school bus fuel economy at an estimated 8 miles per gallon, there are significant savings to be had. The problem with purchasing CNG school buses is the initial capital cost. As of now, the incremental cost is approximately $\$ 40,000$. That is relatively expensive compared to the savings, and the economics do not work out in most cases without the help
 of incentives. If Tiffin City Schools can secure grants for the initial cost of buses, they can save $\$ 2,000-\$ 3,000$ per year on fuel per route running bus.

CNG school bus technology is advancing as the industry grows. New engines are being developed especially for school buses that will bring down the premiums in the future. This development is happening rapidly and Tiffin City Schools should re-evaluate CNG powered buses for replacements on an annual basis.

There is not a significant money saving opportunity for converting the non school bus vehicles at this time. As the price of conversions become more affordable, some of these vehicles could be feasible to convert on a case by case basis.

Conclusion: Converting the bus fleet of Tiffin City Schools is recommended with financial incentives. When the school receives money for conversions the oldest route running buses should be converted first, and new buses would be dedicated CNG powered.

| Tiffin City Schools | Days Per Year | Cost per | Low | Medium | High | Existing Fuel Cost |  |

## Tab 4: Seneca East local Schools

## Seneca East Local Schools CNG Opportunity Analysis

Scheduled Replacements: 6-10 new school buses in the next 5 years

Seneca East Local Schools has a fleet of 20 vehicles. 13 to 14 of these school buses drive daily routes and the remaining buses are kept as backups. These route running buses drive an average of 17,000 miles. Seneca East is a tax exempt school and pays a relatively low price for vehicle fuel at \$3.47 per gallon of diesel. With an estimated fuel economy of a bus at 8 miles per gallon, a CNG powered bus would save a significant amount of money over a diesel bus, between $\$ 2,000$ and $\$ 3,000$, but there are some obstacles to conversion.

One obstacle is that the Seneca East bus garage is located far enough away from Tiffin to not take advantage of a shared fast-fill fueling CNG station. Therefore, Seneca East would
 have to build its own fueling infrastructure to service its bus fleet.

Another obstacle is the CNG incremental cost over a standard diesel bus. Current cost of a CNG bus is about a $\$ 40,000$ premium. At this rate, the cost of conversion would not break even for the school to pay for themselves. When incentives become available for new buses and infrastructure, CNG powered buses will save the district money.

CNG School bus technology is advancing as the industry grows. New engines are being developed, especially for school buses, which will bring down the premiums in the future. This development is happening rapidly and Seneca East's planned replacement buses should leave the option open for CNG.

Conclusion: In order to support CNG buses, Seneca East must build its own time-fill fueling station. It is recommended that Seneca East Local Schools convert its fleet to CNG and build a time-fill station. If Seneca East can procure fueling infrastructure, CNG replacement buses should be evaluated for purchase.

| Cost per | Low | Medium | High |
| :--- | ---: | ---: | ---: |
| GGE | $\$ 1.70$ | $\$ 1.90$ | $\$ 2.20$ |
| DGE | $\$ 1.92$ | $\$ 2.15$ | $\$ 2.49$ |

| Existing Fuel Cost |  |
| :--- | ---: |
| Gasoline | $\$ 3.08$ |
| Diesel | $\$ 3.47$ |

## Tab 5: Seneca County Agency Transportation (SCAT)

## Seneca County Agency Transportation (SCAT) Opportunity Analysis

Scheduled Replacements: 2-3 new transit vans per year

SCAT has a fleet of 26 transit vehicles, with 20 of them based in Tiffin. These vehicles currently fuel at the Seneca County Engineer location. The regular route running vans drive 25,000 to 30,000 miles per year. SCAT is tax exempt and pays a relatively low rate for fuel, $\$ 3.08$ per gallon of gasoline. The fuel economy for these vehicles is roughly 8 MPG . The vehicles are replaced at approximately 200,000 miles.

Even though SCAT pays a low rate for fuel, the vehicles
 are large consumers of gasoline and good candidates for conversion. The paybacks for the vans that are 2010 and newer are favorable and should be considered for conversion. As SCAT purchases new vehicles for replacement, they should also be converted to CNG.

The conversion of a transit van consists of a bi-fuel setup with the CNG tanks mounted under the vehicle. The bi-fuel setup allows the vehicle to be powered by CNG when it is present, and gasoline should the CNG run out.

The SCAT fleet parks inside at their location near SR 100. Therefore, installing time-fill fueling infrastructure is not a viable option.

Conclusion: SCAT in Tiffin has up to 10 vehicles in their fleet that are candidates for conversion and can support a fleet of up to 15 CNG vehicles as they replace older gasoline vehicles with CNG powered models.

## Average Annual Greenhouse Gas Emission Reduction

### 148.1 Metric Tons of $\mathrm{CO}_{2}$

$=$ greenhouse gas emissions of 30.9 passenger vehicles for 1 year
$=\mathrm{CO}_{2}$ emissions from 20.4 homes' electricity use for 1 year
=carbon sequestered by 121 acres of U.S. forests in 1 year

| Total |  |  | $\$ 28,750$ | $\$ 200,000$ |  |

## TAB 6: Arnold Vending

## Arnold Vending Opportunity Analysis

Scheduled Replacements: 5-6 vehicles per year

The vehicle fleet of Arnold Vending consists mainly of Ford cargo vans. Regular route runners typically drive between 20,000 to 30,000 miles per year. Arnold Vending pays about $\$ 3.50$ per gallon of gasoline and the vehicles vary from 8 to 24 MPG in fuel economy. The vehicles are retired when they reach approximately 240,000 miles of service.

The vans are good candidates for conversions but do face some challenges. The main issue is finding enough space for the CNG tanks used in the conversion. Each van is equipped with a refrigerator unit used to transport goods. Together with the unrefrigerated product, it does not leave a lot of room in the back of the van. CNG tanks can be mounted
 underneath the van, but to have enough fuel capacity for their longer routes of around 175 miles, an extra tank may have to be mounted in the cargo area.

The vans park in the same place lined up in a row overnight, which would make installing a time-fill station on the property an option. Unfortunately, the recommended fueling for this system would require that the vehicles be outside. They park inside so they can be loaded with product while parked.

Using current rates and total driving miles of 200,000, the lifetime savings for a converted van would be about $\$ 25,000$ for a dedicated or bi-fuel system. Therefore, the conversion package and size selected for each van will determine whether or not it makes sense to convert them or buy new vans as the vans retire. For example, a van with 100,000 remaining service miles will save $\$ 12,500$ before it is taken off the road. A conversion that will cost $\$ 10,000$ will pay back in its lifetime and save an extra $25 \%$ on fuel. On top of that, some of the installed parts will be able to be used in the next conversion, reducing the initial cost in the future.

Of Arnold Vending's 52 total vehicles, 18 are candidates for immediate conversion. As the older vehicles are retired from service and replaced, new CNG powered vans can take place of the old ones. With the high rate of replacements per year, the fleet alternative powered
 vans could grow to over 30 in 3 years.

Conclusion: Arnold Vending has an opportunity to save money by converting some of its vehicles to CNG now and working in new CNG powered vehicles as older vans are replaced.

## Average Annual Greenhouse Gas Emission Reduction

### 133.2 Metric Tons of $\mathrm{CO}_{2}$

= greenhouse gas emissions of 27.8 passenger vehicles for 1 year
$=\mathrm{CO}_{2}$ emissions from 18.3 homes' electricity use for 1 year
=carbon sequestered by 109 acres of U.S. forests in 1 year

| Year | Vehicles | GGE Used | Annual Savings | Cost | Cash Flow |

## Tab 7: Seneca Medical, Inc.

## Seneca Medical, Inc. Opportunity Analysis

Scheduled Replacements: Replace up to 8 route running vehicles in the next 5 years
Seneca Medical's vehicle fleet consists of straight trucks and tractors based in multiple states. The main fleet is based out of the corporate headquarters located in Tiffin, OH. This fleet consists of 32 vehicles with 22 of them running regular routes that cover over 1.1 million miles per year. Each truck drives an average of 50,000 miles per year at these rates. The trucks are all powered by diesel fuel and are ideal candidates for CNG conversion. Seneca Medical pays $\$ 3.90$ per gallon of diesel and has fueling tanks on site. The straight trucks average 8 MPG of fuel while the tractors
 fuel economy is around 6.5 MPG.

Conversions for these trucks will consist of a dual fuel setup. Straight trucks have more than enough room for the new CNG tanks between the wheels. Capacity of the tanks therefore will only be limited by the necessary amount of CNG needed for each truck's route. The tractors on the other hand do not have the luxury of unlimited room, and therefore will have to have a system designed to balance capacity and storage space on a truck by truck basis.

With a dual fuel conversion averaging 50\% diesel and 50\% CNG, a truck driving 50,000 miles each year will have a payback between 2 and 4 years, not counting the residual value of the conversion kit. With that type of payback, there are 12 available
 vehicles to convert now and the other 10 can be converted over the next 5 years as the older trucks are replaced.

A time-fill fueling station is not an option for Seneca Medical. The trucks park at docks spread around the building when they are not on delivery routes to get loaded/unloaded. Although they are parked outside, it would not be feasible to install the fueling infrastructure around the whole building.

Conclusion: Seneca Medical has an opportunity to save a substantial amount of money by converting its trucking fleet over to CNG. There are 12 vehicles available to convert now, while 10 others can be added over the next 5 years.

## Average Annual Greenhouse Gas Emission Reduction

210.6 Metric Tons of $\mathrm{CO}_{2}$
= greenhouse gas emissions of 43.9 passenger vehicles for 1 year
$=\mathrm{CO}_{2}$ emissions from 29 homes' electricity use for 1 year
$=$ carbon sequestered by 173 acres of U.S. forests in 1 year

| Year | Vehicles | GGE Used | Annual Savings | Cost | Cash Flow |

## Tab 8: TPC Food Service

## TPC Food Service Opportunity Analysis

Scheduled Replacements: 1 new truck per year

TPC Food Service's vehicle fleet consists of 23 vehicles, 14 straight trucks and 9 tractors. Every truck has a diesel refrigeration unit mounted on the front. 18 of the trucks run regular routes year round. Tuesday, Thursday and Friday are the busiest days while Monday and Wednesday tend to be lighter. TPC pays a rate of $\$ 4.02$ per gallon of diesel. The tractors have about 6 MPG fuel economy while the straight trucks run at 8 MPG. Route running trucks drive about
 40,000 miles per year.

With the large amount of miles that these trucks drive and the low fuel economy, TPC has an opportunity to save a significant amount of money by converting its fleet over to CNG. Comparing the CNG payback with the projected remaining life of each vehicle, TPC can convert 10 vehicles immediately and phase in the remaining 8 to CNG as the older vehicles retire over the next 5 years.

These vehicles will have a dual fuel conversion. The refrigerator units that run on diesel will not be affected and will continue to run as they do today. CNG tanks will be added and the trucks will use a 5050 mixture of CNG to diesel for power.

Installing time-fill infrastructure for fueling is not an option for TPC. The vehicles park all around the building at loading docks and too far spread to be effective. Also, the turnaround time may vary for the trucks, making fast-fill stations desirable.

Conclusion: TPC Food Service can convert 10 of its route running trucks to dual fuel while phasing in the remaining route running trucks. The 8 remaining vehicles should be phased in as the existing diesel trucks are retired. After 5 years, TPC Food Service could have a fleet of 15 CNG powered vehicles.

## Average Annual Greenhouse Gas Emission Reduction

### 141.5 Metric Tons of $\mathrm{CO}_{2}$

= greenhouse gas emissions of 29.5 passenger vehicles for 1 year
$=\mathrm{CO}_{2}$ emissions from 19.5 homes' electricity use for 1 year
=carbon sequestered by 116 acres of U.S. forests in 1 year

| Year | Vehicles | GGE Used | Annual Savings | Cost | Cash Flow |
| :---: | :---: | :---: | :---: | ---: | ---: |
| 1 | 10 | 32,750 | $\$ 45,000$ | $\$ 160,000$ | $-\$ 115,000$ |

## CONCLUSION

## Conclusion

There is a significant opportunity to introduce an alternative fuel to the community of Tiffin. It allows both the private and public sectors significant savings in transportation and operational cost. Availability of an alternative fueling option increases the competitiveness of the region promoting future job growth while at the same time supporting the existing community and businesses.

With the NCOESC collaborative funding the construction of fueling infrastructure, the burden of significant capital investment from the private sector has been eliminated. With reduced capital outlay and the reduction in fuel spend by $40-60 \%$, private businesses will see a competitive advantage in their respective markets. The conversion from diesel/gasoline to CNG is environmentally friendly and can be used as added value when soliciting new business.

By reducing transportation fuel by 40-60\% the public sector partner's show their constituents that they take cost reduction seriously, and are thinking "outside the box" to keep taxes at a minimum. Local government is reminding their constituents that there are technologies to reduce their carbon footprint, while being fiscally responsible.

Gasoline and diesel as the traditional fuel source for American automobiles has come under increasing pressure as a commodity. Geo-political events, especially in the Middle East, and the hedging of petroleum products on the international market, have made oil an unstable commodity for the last 20 years. One example of this is the average cost of diesel doubling from $\$ 2$ in 2008 to $\$ 4$ per gallon today. Fleet managers are always looking to reduce operating costs and alternative fuels have become a viable solution. Natural gas is reliable, domestic, safe, clean and sustainable. Most importantly, the stable and relatively low long term cost projections for natural gas prove CNG is a vehicle fuel of the future.
